Interpretation :

Thyroid Stimulating Hormone is a glycoprotein with two – covalently bound subunits.The alpha subunit is similar to those of follicle stimulating hormone (FSH), human chorionic gonadotrophin (hCG) and Luteinizing Hormone (LH).The beta submit of TSH is unique, which results in the specific biochemical and immunological properties of this hormone.TSH is synthesized and secreted by the anterior pituitary in response to a negative feedback mechanism involving concentrations of FT3 (Free T3) and FT4 (Free T4).Additionally, the hypothalamic tripeptide, thyrotropoin – releasing hormone (TSH), directly stimulates TSH production.TSH interacts with specific cell receptors on the thyroid cell surface and exerts two main actions.The first action is to stimulate cell reproduction and hypertrophy.Secondly,TSH stimulates the thyroid gland to synthesize and secrete T3 and T4 .In primary hypothyroidism, TSH levels are significantly elevated, while in secondary and tertiary hypothyroidism TSH levels are low.

Below mentioned are the guidelines for pregnent woman related reference ranges of TSH recomemded by Americal Thyroid Association:

Pregnancy	uIU/mL
First Trimester	0.600 - 3.400
Second Trimester	0.370 - 3.600
Third Trimester	0.380 - 4.040

REMARKS

In vitro quantitative determination of **HbA1c** in whole blood is utilized in long term monitoring of glycemia.The **HbA1c** level correlates with the mean glucose concentration prevailing in the course of the patient's recent history (approx - 6-8 weeks) and therefore provides much more reliable information for glycemia monitoring than do determinations of blood glucose or urinary glucose. It is recommended that the determination of **HbA1c** be performed at intervals of 4-6 weeks during Diabetes Mellitus therapy. Results of **HbA1c** should be assessed in conjunction with the patient's medical history, clinical examinations and other findings.
